¹CE Department, ITU

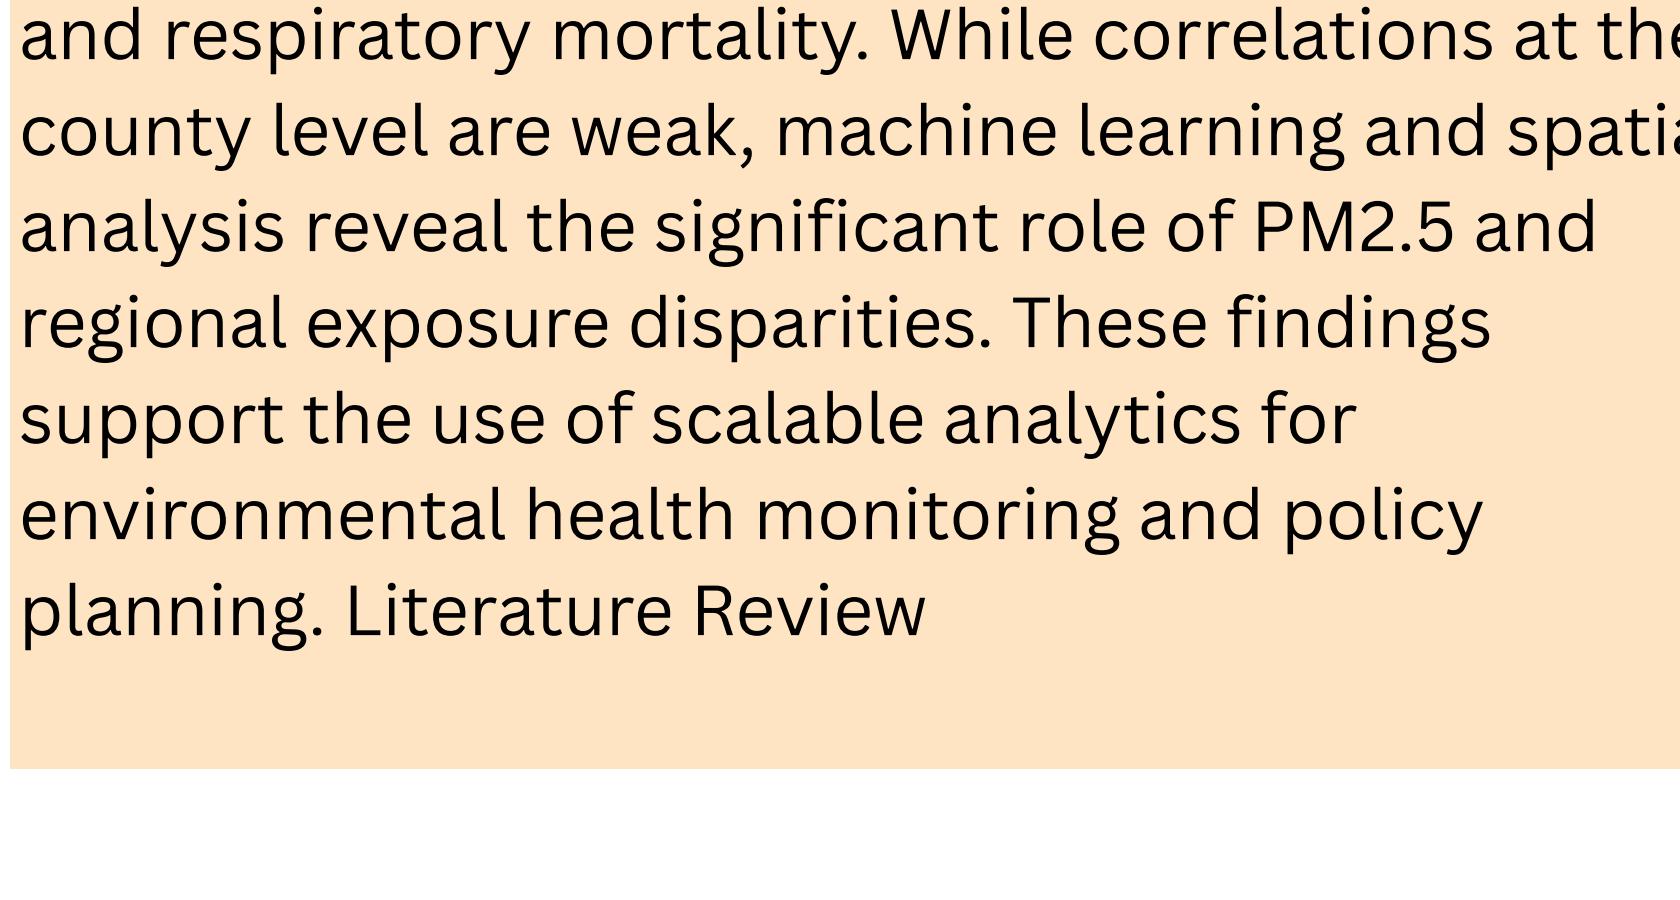

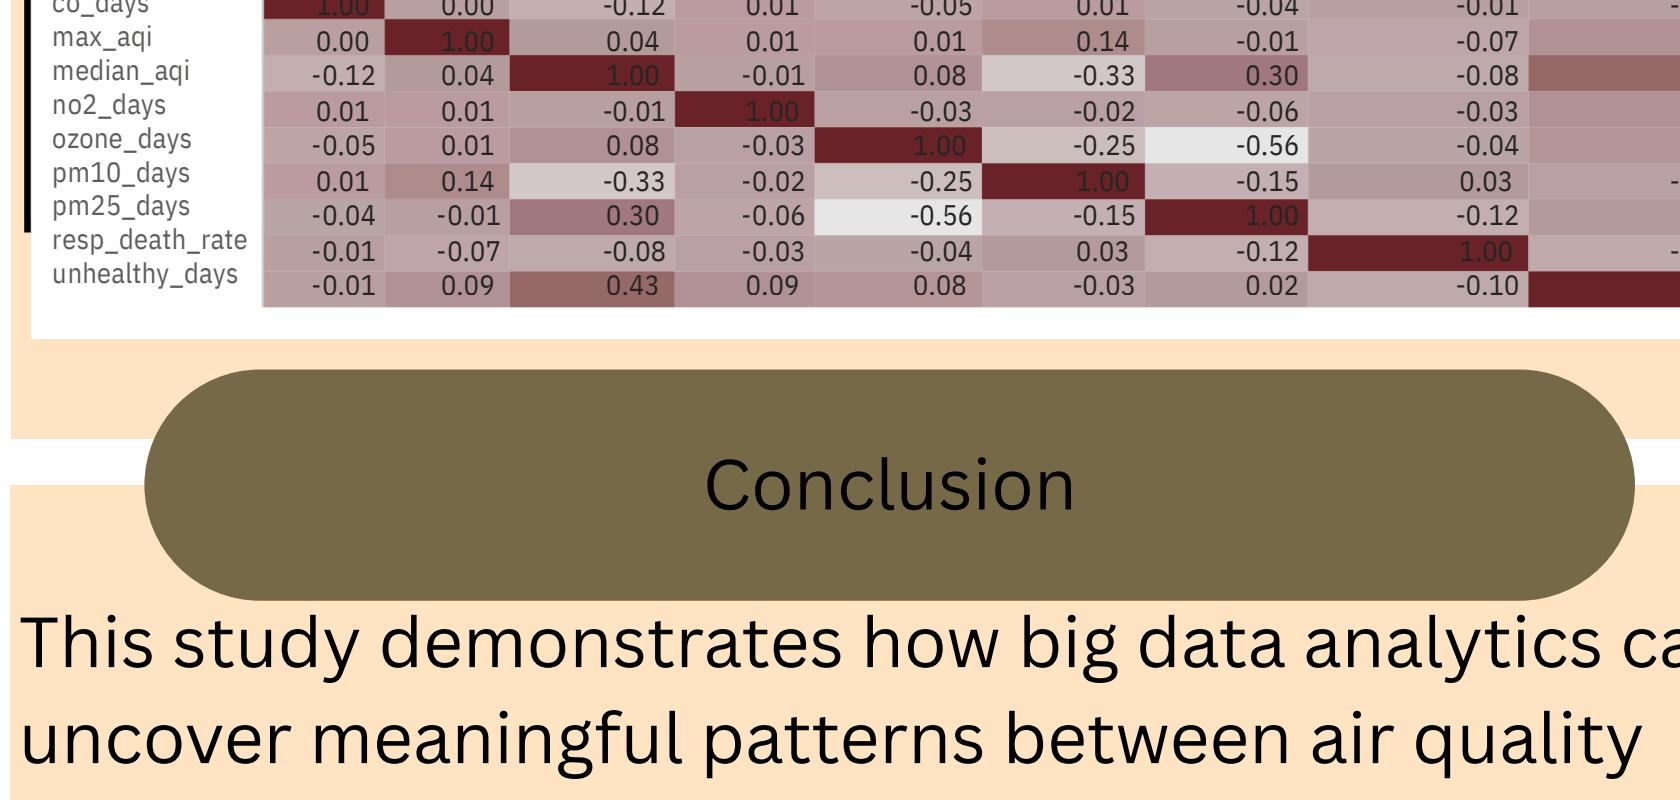

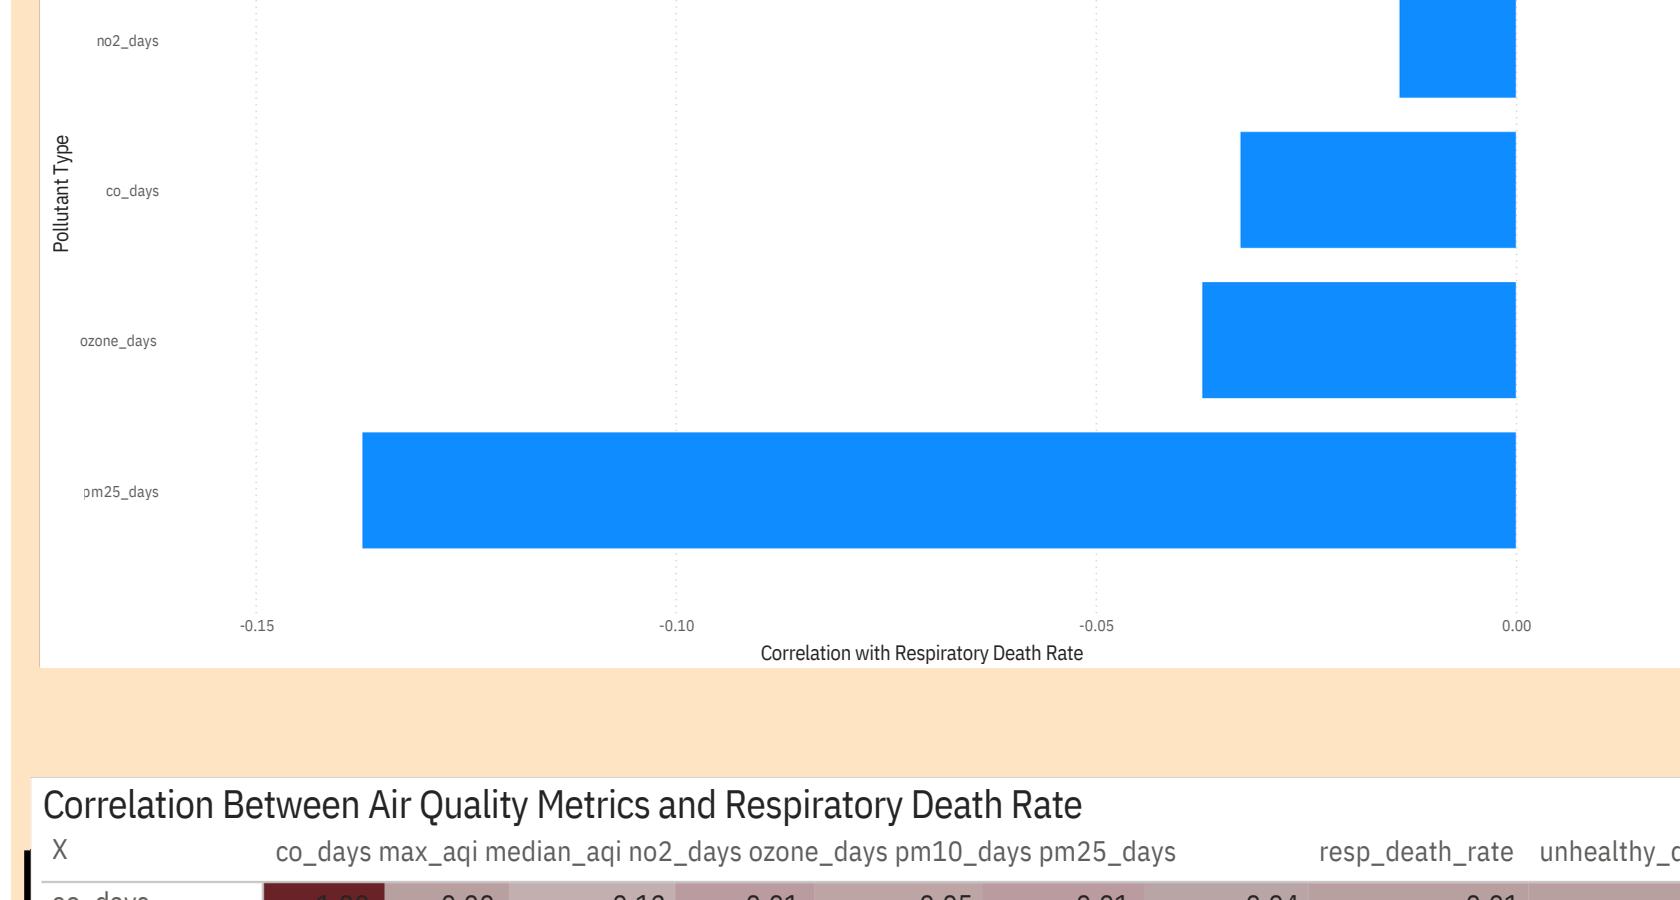

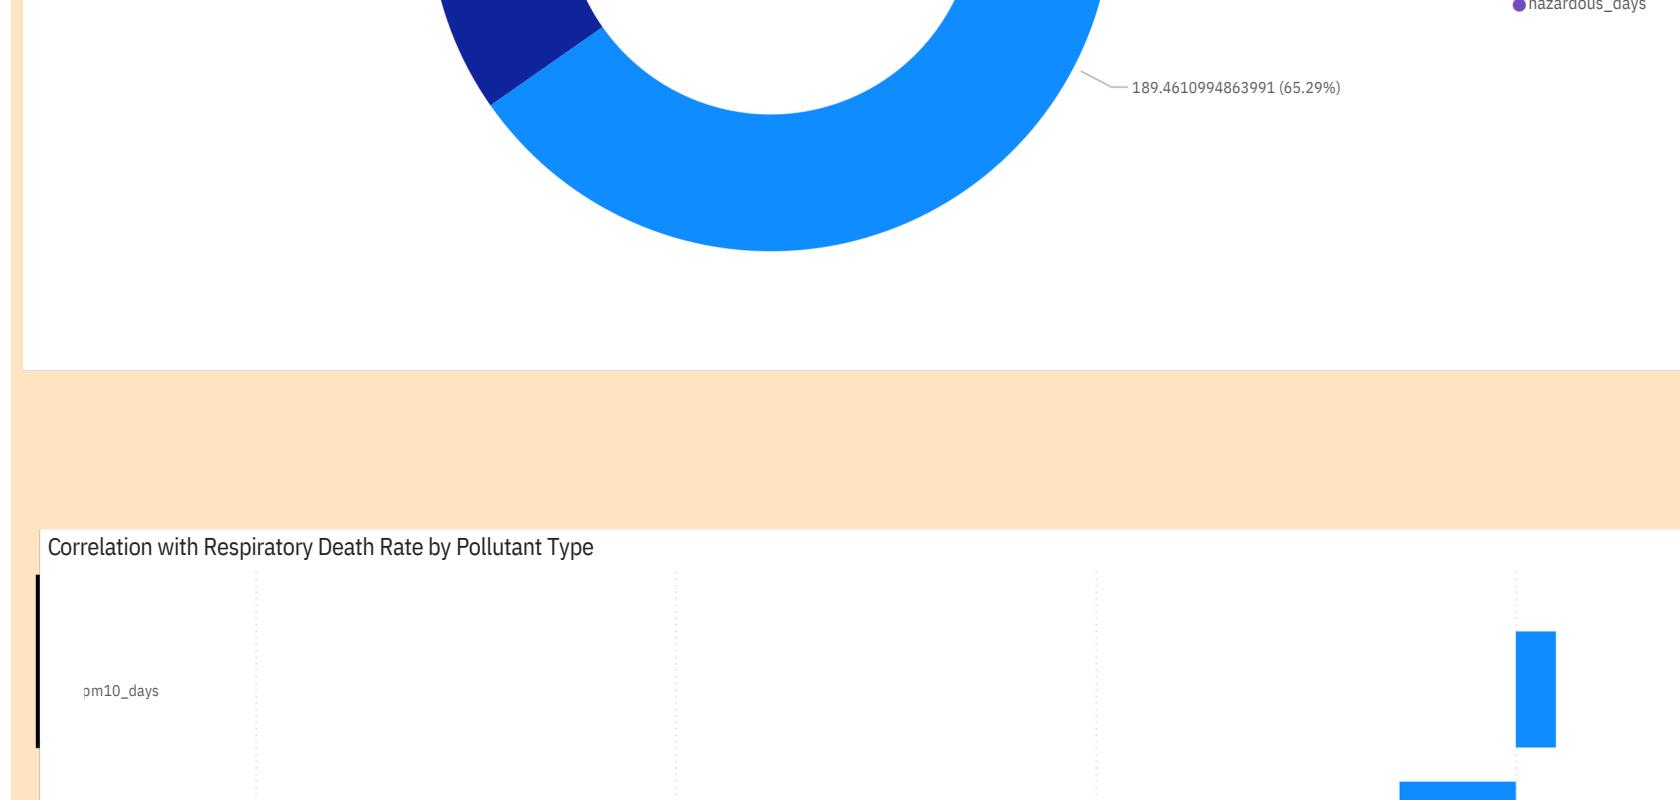

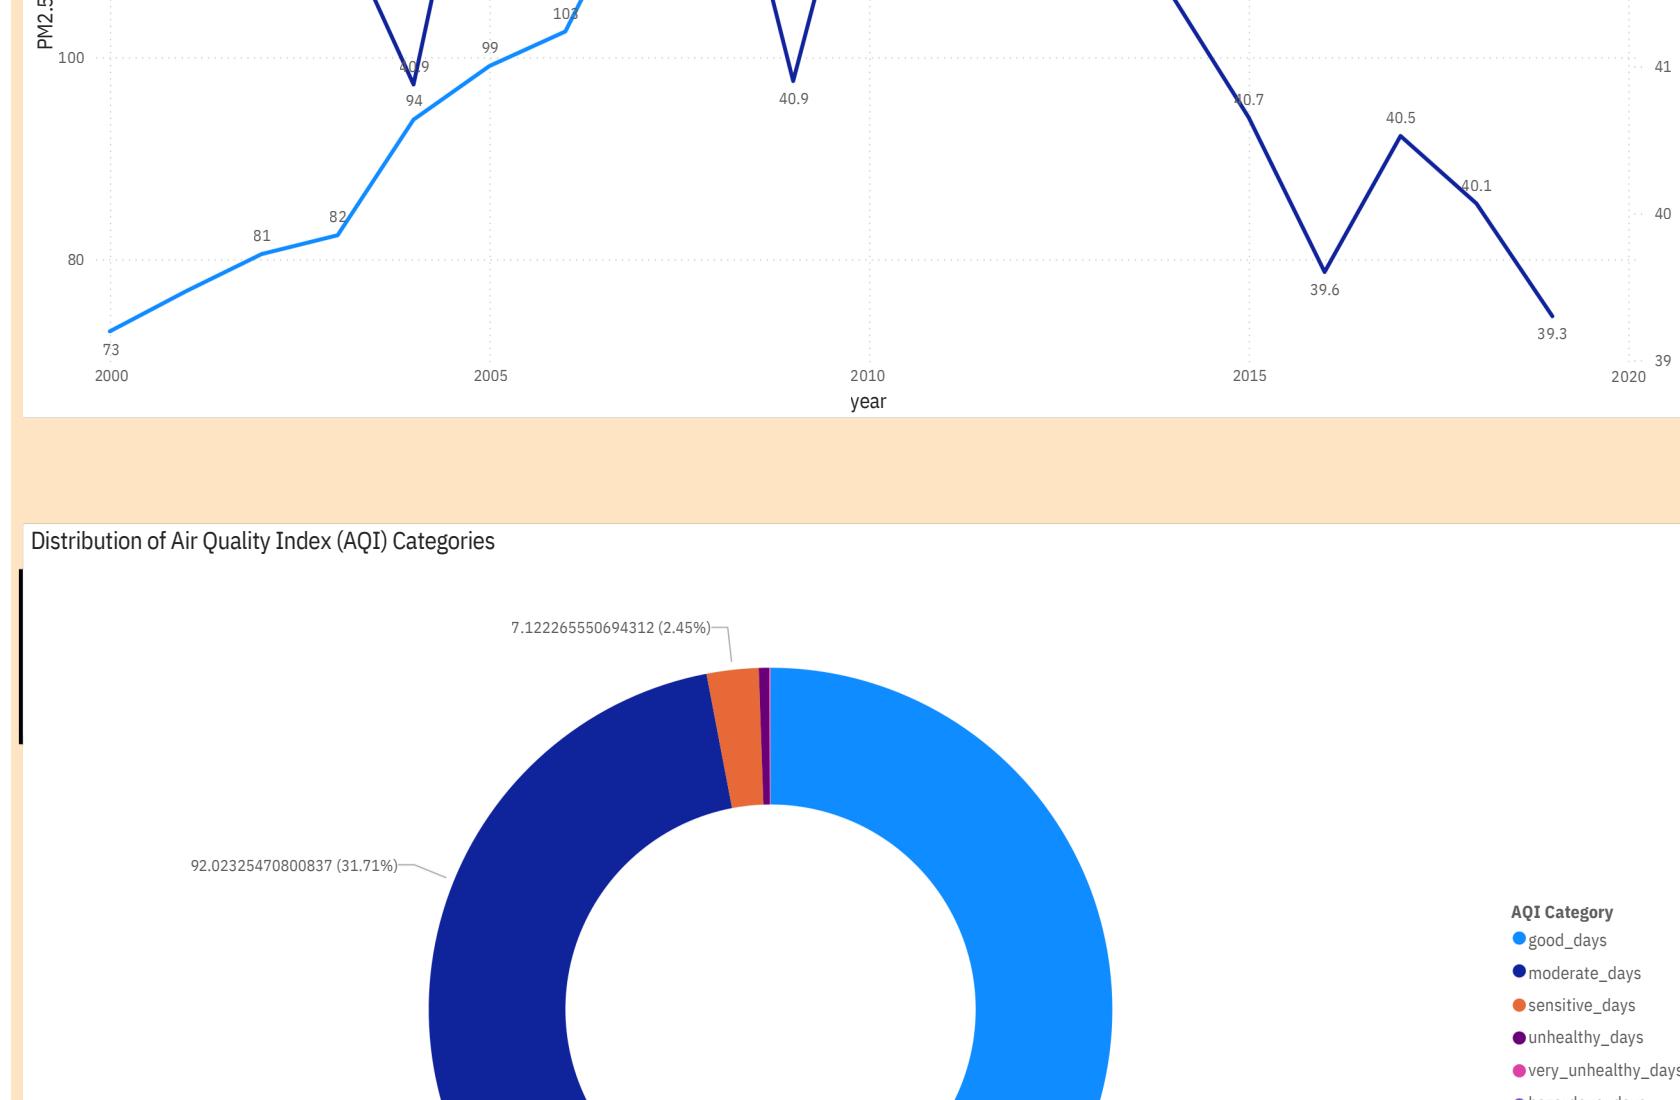

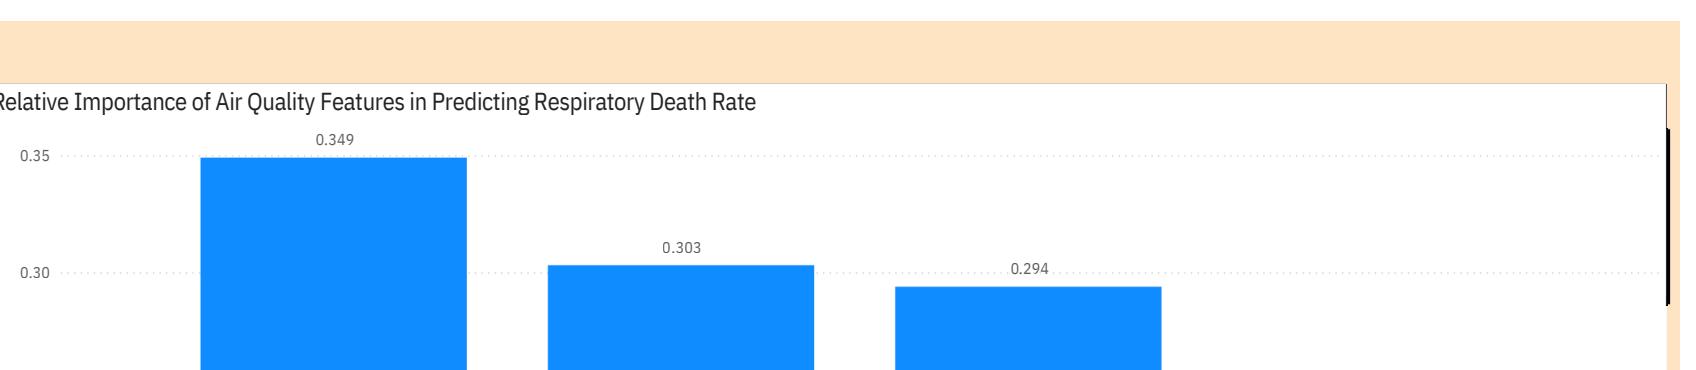

Abstract

Air pollution is a major public health concern worldwide. This study analyzes the relationship between air quality indicators and respiratory death rates across counties using large-scale AQI data. Distributed data processing with Dask was employed to handle multi-year, multi-regional data efficiently. Statistical analysis and machine learning models were applied to identify trends, pollutant impacts, and spatial patterns. Results highlight the role of PM2.5 exposure and regional disparities in respiratory mortality, emphasizing the need for data-driven environmental health policies.

Literature Review

- Prolonged exposure to poor air quality is linked to respiratory diseases such as asthma, COPD, and lung cancer.
- PM2.5 and ozone are consistently identified as major contributors to respiratory mortality.
- Air Quality Index (AQI) is widely used as a population-level indicator of pollution exposure.
- Prior studies often rely on small datasets; scalable analytics remain limited.

Methodology
